BACKGROUND OF THE INVENTION

15

(0003) The present invention relates to means to provide an improved fuel burning element, such as a candle or lamp, which consumes fuel more efficiently while presenting an improved means for distribution of volatile materials, while also providing an improved degree of safety while burning, and a candle holder
20 which requires little or no cleaning to remove wax residue. The candles or lamps of the present invention comprise a solid fuel element located on a melting plate, a preferably consumable wick, and heat conductive means in the wick holder to transfer heat from the burning fuel, i.e. the flame, to the remaining fuel, thereby assuring its more rapid and complete melting, and both control and uniformity of
25 the temperature of the melted pool of fuel. The melting plate incorporates a capillary lobe which cooperatively engages either or both of the wick holder and the fuel element in such a manner as to assure exact placement of both at the best position on the melting plate, while creating a capillary effect to feed melted fuel to the wick for efficient consumption. Such a configuration has been found to
30 provide improved means to control the transfer of heat generated by a candle flame, and to provide an improved degree of safety for the burning of candles, such as votive candles. Specifically, the preferred embodiment of the present

invention comprises the use of a capillary lobe at or near the center of the melting plate of a melting plate candle, said capillary lobe cooperatively engaging a complementarily shaped wick holder having a heat conductive fin. By virtue of this combination of capillary lobe and cooperative wick holder, applicants have
5 provided a candle in which the flame of the candle remains essentially at the same height, relative to the surface upon which the candle holder is placed.

(0004) Ordinary candles comprise a vertical, self-supporting body or column of wax, with a substantially horizontal top and a central longitudinal wick which extends through and above the wax. The exposed portion of the wick
10 above the solid wax is lighted by a flame, and the heat generated by the flame melts a small volume of the wax at the top of the candle, adjacent the wick, establishing a puddle or reservoir of molten wax to serve as fuel for the flame on the wick, and to release any volatile actives present therein. The capillary attraction of the molten wax and the wick, which is generally a structure of closely re-
15 lated fibers, causes the molten wax to travel through the wick to the flame, by which it is consumed. As the wax is consumed in this manner, the body of wax diminishes and the top surface thereof progressively lowers. The upper portion of the wick, extending above the lowering wax, is generally consumed by the flame.

The flame in such a candle remains in the same position relative to height, from
20 the start to the end of the burn, at which time all of the wax has been consumed.

(0005) Also well known are such candles as votive candles and tea lights. For purpose of discussion, tea lights shall be considered to be relatively small candles in which a body of paraffin is located in a container, having a wick centrally disposed, while votive candles shall be considered to be candles of similar
25 size provided without a container. At the lower end of the wick is typically found a wick clip having a flat horizontal bottom surface, which functions to retain the wick in its perpendicular position, even as the paraffin is melted and liquified by the heat of the flame. In most such votive candles and tea lights, the wick is a cotton material saturated with paraffin, and burns with the paraffin, thus being
30 consumable. In such candles, or lights or warmers employing the same, the visible flame moves lower, or closer to the bottom surface of the container as the fuel and wick are consumed, down to the level of the bottom of the wick. Further,

after consumption of all of the wax above this point in the unit, the container (of the tea light), the unburned wax, and the wick clip remain to be disposed of by the consumer. As a safety consideration in such candles, the wick is normally crimped or terminated at a point about 0.25 inches above the bottom of the wax, so as to cause the flame to extinguish above the bottom of the container, and to thus prevent the heat of the flame from reaching the surface upon which the candle is positioned, preventing damage to such surface, and reducing the likelihood of igniting possible contaminants such as burnt matchsticks remaining at the bottom of the candle, or carbonaceous remains of the consumable wick.

Such an arrangement also has the detriment of leaving a small volume of unburned wax in the bottom of the container when the flame extinguishes.

(0006) Similarly, liquid fuel lamps are known in which a wick is supported with one end suspended in a reservoir of liquid fuel, such as lamp oil. By capillary action, the liquid fuel rises through the wick to the upper end thereof, where it is subjected to consumption by a flame. As fuel is consumed by the flame, additional fuel rises through the wick by capillary action to feed and maintain the flame. Permanent, or non-consumable, wicks are most frequently employed for this type of lamp.

(0007) In U. S. Patent No. 4,557,687, Schirneker teaches a fuel element comprising a shell-like elongated housing in which a supply of fuel may be placed, with a non-consumable wick immersed in the fuel supply with its upper portion protruding from the top of the housing. When the fuel is a solid fuel, such as paraffin, the wick must conduct heat into the housing of the fuel in the area of the immersed wick to thereby melt the solid fuel so as to provide sufficient amounts of molten paraffin to be drawn up in the wick. Such conductivity may be obtained by means of a piece of metal embedded in the wick. The purpose of the fuel element is to provide a simulated log for a fireplace which does not require a chimney.

(0008) Neil, in US 4,206,500, teaches a candle having a metal stiffener which fits within the wick. The stiffener is supported by a flat base portion large enough to render the wick free-standing by supporting the weight of the non-consumable wick.

(0009) In U. S. Patent No. 3,741,711, Bryant teaches a composite decorative candle formed of clear, undyed and unpigmented candle wax in any appropriate candle shape, provided with a centrally recessed glass cylinder into which a replaceable small candle may be placed. Thus, the decorative outer candle
5 may have a refill unit, such as a votive candle or tea light, placed therein to provide indefinite reusability. If the outer candle body comprises surface ornamentation, a luminescent glow through the candle body results when the inner candle is burned, and the outer candle is not consumed.

(0010) U.S. Patent 3,910,753, of Lee, discloses a wax burner comprising a
10 vessel having a heat conducting metal heat sink surrounding and supporting a wick which projects upwardly, and has a heat conductive metal core means conducting heat into the heat sink, which acts as a wax melting surface. The wax burner may be fueled by paraffin wax or other suitable solid fuel, which may be added to the melting surface as required. The burner may constitute one or
15 more units. In Lee, however, the fuel is neither supported nor contained by the heat sink, which is configured much like a spool, with upper and lower flanges, or upper and lower flat horizontal surfaces. The upper flange or upper surface acts as a heating surface, while the lower flange serves as a base for the heat sink, engaging the bottom surface of the burner vessel. Slots in the vertical surface of
20 the heat sink provide means for the wax, melted by the heat sink, to flow from the exterior surface thereof to the internally located wick. Since the wick structure of the patent includes a metal core and a heat conductive metal sleeve about the wick, the wick structure is an integral portion of the heat sink of the burner assembly, is non-consumable, and requires priming with wax prior to its first use. In
25 use, solid wax is added to the heating surface, and replenished as necessary, or the entire vessel may be filled with wax. It is to be noted that the vessel itself is not used to conduct heat to the fuel, but only to contain it, and that a separate heat transfer system, i.e. the heat sink structure, which is independent of and distinct from the heat radiated by the flame itself, is utilized to achieve burning of
30 the wax fuel. Even with this added heat transfer mechanism to assist in melting of the fuel, complete utilization of all of the fuel in the vessel is unachievable, even when the burner is permitted to burn to self-extinction, in view of the relative

positioning of the lower flange and the wax conducting means of the heat sink (i.e. slots in the vertical surface thereof, above the lower flange).

(0011) In U.S. Patent No. 2,713,256, Oesterle et al teach a votive candle having a wick extending downward in the bottom of the candle into a tapered
5 central body projection, where said wick engages an adapter inserted into a cup provided to hold the votive. The adapter is provided with means to support the wick of the candle until the candle has completely burnt out, thereby leaving no wax or wick residue in the cup, enabling a new candle to be inserted into the cup without removal of the adapter. The adapter does not function to provide a more
10 even or uniform burning of the candle, but merely to provide a proper positioning of the votive candle. When placed over the adapter, and the upwardly directed tube thereof, the flame on the wick comes into contact with a wicking material retained in the base of the tube, so as to ignite such wicking and assure that all of the melted wax is burned, thus leaving a clean cup containing no remains of
15 the previous candle when a new candle is put in place.

(0012) European Patent Application EP 1 054 054 A1, published November 22, 2000, teaches a candle having a wick holder assembly for candles to be used on a supporting surface, wherein the wick holder provides enhanced control over heat transfer from the flame to the supporting surface upon which the can-
20 dle rests. In this patent, the object of the wick holder assembly is to dissipate heat from the flame away from the support surface, essentially the opposite of the goal of the present invention.

(0013) A number of additional patents teach the use of heat conductive elements to liquify solid fuel for consumption at a wick, or to dispense an element
25 such as a fragrance or insect control material. These include U. S. Patents 5,078,591 of Despres; 4,755,135 of Kwok; and 5,425,633 of Cole; as well as PCT Application WO 89/06141, assigned to Lamplight Farms, Inc. In addition, numerous patents teach various modifications of candles, but fail to teach the combination set forth in the present invention.

30 (0014) The present invention provides a candle or lamp device capable of rapidly and completely melting a solid fuel to form a large liquid pool, thereby improving distribution of any volatile materials present in the fuel, and ensuring effi-

cient and complete utilization of all of the fuel provided, while providing increased safety and convenient refilling. Further, the concept of the present invention offers highly decorative as well as functional candles and lamps, which may utilize a variety of gel and solid fuels, with the significant advantages of permitting rapid and convenient replacement of one fuel element by another at the whim of the consumer, without the need to clean or scrape the container in which said candle is utilized to remove a body of unburned fuel after the fuel element has been consumed.

BRIEF SUMMARY OF THE INVENTION

(0015) As utilized herein, the term melting plate candle shall encompass the combination of a solid fuel element and a heat conductive container or holder for the fuel. The terms fuel container and fuel holder shall be meant to encompass a support plate or melting plate comprising means to contain and melt the fuel element, a wick and wick holder engaging said support plate, and heat conductive elements, such as fins, referred to hereinafter as either wick fins or heat fins, and/or the skirt or base of the wick holder, to transfer heat from a flame upon said wick to said melting plate. Thus, the support plate functions to hold the fuel element, to retain the wick holder, and to conduct heat to the solid fuel element to thereby melt said fuel element to provide a liquid fuel to feed to the flame via the wick. Moreover, the base portion, i.e. the skirt or base, of the wick holder engages a lobe on the surface of said support or melting plate in such a manner as to transport said liquid fuel to the wick by capillary action. Accordingly, the manufacturer may provide melting plate devices, wicks and wick holder assemblies, and solid fuel elements, together, or independently (separately), and the consumer may join the separate elements to form a melting plate candle or fuel burner, with the option to change wicks and fuel elements at will. In the preferred embodiment of the invention, the wick, wick holder, and fuel element shall be provided as a single replacement unit to be utilized with a separately provided melting plate.

(0016) A key element of the present invention constitutes the capillary lobe on the melting plate, which lobe provides a locating device for a complementarily shaped wick holder, creates a site for capillary feed of fuel to the wick, and provides a means for heat transfer from the flame to both the melting plate and the solid fuel. The wick holder, in addition to providing a mounting means for the wick, has a base which conforms to the capillary lobe in such a manner as to create a capillary feed by which melted wax flows to the wick as fuel. In addition to the base or skirt of the wick holder being a heat conductive element, the wick holder may also provide an additional heat conductive element such as a fin, which may be in close proximity to, or in contact with the flame, and thereby conduct heat back to the wick holder base, and thus the capillary lobe, and thereby to both the melting plate and the fuel. It is to be understood that this arrangement of elements provides for much greater control of the degree of heating of the pool of melted wax, and the pool temperature, by virtue of the ability to control the amount of heat conducted to the pool by either the skirt of the wick holder or by the fins thereof, This may be accomplished by selection of the number of fins, for example, or control of the conductivity thereof, such as by choice of position relative to the flame, or material of construction. This in turn is most important in candles which dispense a volatile material, such as a fragrance, where a rapid temperature rise to the most effective temperature for volatilization of the active material is desired. Such a rapid temperature rise clearly results in a more rapid melt of the fuel element, and a more rapid dispensing of volatile material. In fact, with the present invention, it is possible to tailor a melting plate candle to a specific volatile active to be contained within a fuel element, by permitting control of the amount of heat conducted to the pool of melted fuel, and thus controlling the temperature thereof.

(0017) Alternative aspects of the present invention provide for the fuel element to be provided as a separate element which is complementarily shaped relative to the wick holder, so as to fit around the wick holder in its position on the capillary lobe of the melting plate. While it is possible for a permanent wick and wick holder assembly to be provided as a part of the melting plate, in the preferred embodiment of the invention the wick holder and fuel element are provided

to the consumer as a single unit, or as individual separate units to be combined with the melting plate. In this manner, wick holders of differing shape and configuration may be combined with fuel elements of appropriate configuration which differ in color or scent, for example.

30

DETAILED DESCRIPTION OF THE INVENTION

(0026) The present invention provides a means for the burning of solid fuel elements, wherein said means ensure the maximum utilization of the solid fuel provided. The melting plate devices of the present invention comprise a container for solid or gel fuels, and a wick holder comprising a wick and optional heat transfer elements. These devices provide an improved transfer of heat from a heat source, *i.e.* a flame burning the fuel at the wick, to the remaining fuel and, more importantly, back to the container holding said fuel. Such devices are preferably both functional and designed so as to be decorative or esthetically pleasing.

(0027) The melting plate candle of the present invention comprises a fuel element, and a container encompassing the fuel, said container comprising a heat conductive support plate, or melting plate, in direct contact and in supporting or containing relationship, with the fuel element. The melting plate candle of the present invention may further comprise additional heat transfer elements, in either or both of the heat plate and the wick holder, to deliver heat by conductive means to the fuel and to the melting plate, in addition to that heat transfer obtained to the melting plate by direct radiation from the flame. Such conductive elements result in improved transfer of heat from the burning wick to both the fuel and the melting plate with which the fuel is in contact, thereby heating the fuel over a relatively larger surface. This, in turn, provides for more rapid melting of solid and gel fuels, and more rapid heating of the thus melted fuels, to provide a more uniformly heated pool of fuel, as well as greater control of temperature of the melted pool of fuel, allowing optimization of volatilization of actives present in the fuel. A result of the present invention is more rapid heating of the liquefied pool of fuel to temperatures which are not readily achieved by a conventional candle or lamp, so as to more rapidly and fully melt the solid fuel and to improve consumption of the fuel. The melting plate element thus functions as a heating plate for the fuel element and the melted fuel. As such, it is evident that the melting plate is preferably comprised of a heat conductive material, such as a metal, although less conductive materials, such as glass or ceramic may be em-

ployed with less efficiency due to less conductivity. The preferred material for use as the melting plate is polished aluminum, due to its high efficiency as a conductor of heat, its light weight, and for aesthetic reasons. It is also possible that the melting plate may constitute a non-conductive body having a conductive surface applied thereto, such as a less conductive surface having a thin layer of metal applied thereto. In this regard, it is noted that the surface of the melting plate may have a coating of a surface tension modifying material applied thereto for purposes of preparing a self cleaning or easy cleaning melting plate. For example, a thin layer of a polytetrafluoroethylene material may be applied over a rough surface to provide a smooth wetting surface upon which molten wax will flow easily, and which will enable easy removal of solidified wax upon extinguishing the flame and allowing the candle to cool.

(0028) The melting plate, which thus acts both as a fuel container and a heat transfer means to heat the fuel, is shaped so as to collect the melted or liquified fuel at its lowest point, at which point a wick is preferably located by means of a wick holder positioned upon a capillary lobe, so as to ensure that all fuel is fed to the wick, whereby the maximum consumption of the fuel is achieved. Thus, the melting plate is preferably shaped as a bowl, or in the form of a funnel, with the lowest portion thereof preferably, but not necessarily, centered. The entire interior surface of the fuel container is preferably highly heat conductive, and supports, contains, and heats the fuel, although containers in which only a small portion of the interior surface acts as a melting plate are within the scope of the present invention. Candles employing such melting plates shall be referred to, collectively, as melting plate candles. The melting plate itself may, of course, be essentially flat, with raised edges or a surrounding wall to contain the melted fuel.

(0029) Moreover, the melting plate helps to control the shape and depth of the pool of fuel which is burned at the wick, and to maintain the constancy thereof. It is to be understood that the fuel utilized in the present invention may be initially in solid or gel form, but must be in liquid form for moving up the wick by capillary action to the flame, where it is consumed. Thus, the fuel used with the melting plate candle shall be such that it will not be transported by wicking

action at ambient or room temperature, but requires heating to a liquified state, i.e. melting, to be subject to capillary or wicking action. For convenience, the term solid fuel shall be used hereinafter to refer to fuel in either a gel or conventional solid state, such as conventional candle wax, preferably in the form of a hard, shaped body or "puck" of wax. It is also to be understood that the fuel consumed in the flame at the burning wick is drawn by the wick from a liquid pool of fuel, which pool is formed by melting the solid fuel, and heating said liquid pool by conductive heat transfer from the melting plate and heat exchange elements, in addition to the radiant heat from the flame on the wick. By the use of the melting plate technology of the present invention in addition to the conventional radiant heating of the surface of the fuel, the size, volume, depth, and temperature of the liquid pool of fuel are better regulated. And, as a result of greater control of heat transfer to the fuel, a melted, liquid pool thereof is more rapidly formed and heated to a desired temperature. Because the speed of achieving a uniformly heated liquid pool of fuel is increased, a more efficient consumption of the fuel results, and a more complete usage of available fuel due to the decrease of fuel left unburned on the surface of the melting plate, as well as a more efficient release of any volatile active materials in said fuel, such as fragrances. In preferred embodiments of the present invention, a pool of liquid, i.e. melted, fuel rests upon the surface of the heat conductive melting plate. This pool of fuel may initially contain unmelted fuel in the solid state, as well as melted fuel, and the elevated temperature of the pool achieved by the present invention aids in assuring a complete melting of the solid wax puck and complete and optimized dispersal of any volatile active materials present in the fuel. As a comparison to a conventional candle, it may be seen that in the conventional candle, the wax melts around the flame at the top of the wick, and as the wick is consumed, the flame moves downwardly. In the present invention, the wax melts around the flame, but the end of the wick is at a relatively constant height, and the flame does not move significantly downward. As a result, a more aesthetically pleasing candle is provided.

(0030) Generally, the melting plate device embodies both a melting plate and secondary heat conductive elements, which secondary elements may be

part of the wick holder and in close proximity to the flame, to ensure more uniform and rapid distribution of heat from the flame upon the wick. The wick is affixed in its preferred position by means of the wick holder. The wick, which is preferably a consumable wick, may be any filamentary body which is sufficiently sturdy, which will burn with a steady flame, and which is capable of drawing up the molten candle fuel by capillary action. Such a wick may be of any conventional consumable wick material, such as cotton, cellulose, nylon, or paper, but may be non-consumable as well. The wick holder and wick may preferably be located in the center of the candle, or may be off-center as desired. The presence of two or more wicks, and associated wick holders and capillary lobes, is also within the scope of the present invention. In the present invention, the wick is positioned in a wick holder which engages the melting plate by means of an appropriately located capillary lobe on the melting plate, which serves to locate the wick holder (and thus, the wick), to transmit heat from the flame on the wick to both the fuel and the melting plate, and by means of the capillary nature of the appropriately sized gap formed by the fit of the lobe in relationship to the wick holder, to enhance flow of fuel to the wick. Moreover, the wick holder is preferably configured so as to engage the fuel element in a lock and key relationship and to position it on the melting plate in the preferred location.

(0031) The primary heat conductive element constitutes the melting plate itself, which may comprise portions formed, raised, or bent to be in closer proximity to the flame, such as a raised section of the plate, e.g. the upper edge of the raised side of the melting plate. For example, the melting plate may constitute a bowl shaped container having its outer periphery in close proximity to the flame, such as a container in which the side wall of the bowl is formed so that the lip of the upper opening curves back toward the center of the bowl, and thus toward the flame. The melting plate may also have secondary heat conductive elements, such as one or more raised portions which act not only to absorb and distribute heat by conduction, but to channel or direct the flow of liquid fuel to the wick. Such raised portions may constitute areas of material having higher heat conductivity than surrounding areas of the container. In such examples, the support plate may comprise a less conductive material, such as glass, and the pri-

mary heat exchange may be by radiant heat and conducted heat by means of the secondary heat conductive elements of the wick holder. It may thus be seen that the wick holder assembly, comprising a wick, and a fuel element, in conjunction with a base configured so as to complementarily engage a capillary lobe, may be utilized in any candle container comprising a capillary lobe.

(0032) In the present invention, a capillary lobe both engages and positions the aforementioned wick, wick holder, and fuel element in such a manner as to provide the most advantageous positioning thereof, as well as to create a capillary flow of melted fuel from the melting plate to the wick positioned in the wick holder, which is placed in such close relationship to the capillary lobe as to create a very narrow gap between the lobe and the wick holder. By virtue of this narrow gap, which may be from approximately 0.01 to about 0.04 inches, preferably about 0.02 inches, liquefied fuel rises to the wick for consumption. It should be noted that it is within the scope of the invention that the capillary action may be the result of grooves cut in the lobe, or in the wick holder, and that the wick holder may be held away from the lobe by the presence of appropriately positioned and sized bumps located on either the lobe, the wick holder, or the melting plate. Moreover, the capillary forming combination of elements may constitute a concave depression in the melting plate, rather than a raised male lobe, and the wick holder in such case may be an appropriately shaped male member which fits closely within the depression so as to create a capillary gap between the members, by which fuel is fed to the wick. Still further, it is contemplated that the capillary lobe, either in a male configuration or in a female configuration, need not constitute a raised circular member, but may be of any shape, such as for example cylindrical, pyramid shaped, square, oval, triangular, or any other desired shape, in combination with a like-shaped and appropriately dimensioned wick holder. It is also to be noted that the capillary lobe need not transmit liquid fuel to the wick at all parts of the perimeter of the capillary lobe. For example, a circular capillary lobe in conjunction with a circular wick holder need only create a capillary gap for a limited portion of its circumference, such as for 90, 180, or 270 degrees. Thus, the wick holder need not be in a close enough proximity to the lobe throughout the total area of engagement therewith to provide a full capillary

effect, but only in sufficient area to provide an adequate flow of fuel to the wick to maintain the flame upon said wick.

(0033) Additional secondary heat conductive elements may be separate assemblies which are utilized in conjunction with the melting plate and consum-
5 able wick and wick holder. The secondary heat conductive element may take the form of heat fins or heat conductive surfaces attached to the wick holder, and having either vertical or horizontal orientation or elements of both. In preferred embodiments, such heat conductive elements are heated by contact with the flame, or by heat radiation from the flame, and conduct such heat to both the
10 melting plate and to the fuel so as to more efficiently heat the fuel. The secondary heat conductive elements of the wick holder, hereinafter exemplified as heating fins, although not limited to fins per se, and intended to encompass other heat conductive extensions of the wick holder which may serve this function, may be of any heat conductive material, and may be either formed as an exten-
15 sion of the wick holder or joined to said wick holder in such a manner as to conduct heat from the flame to that portion of the wick holder which is engaged by the capillary lobe and/or the melting plate. The wick holder thus comprises fins, a means to hold the wick, the wick, and a base configured so as to engage the capillary lobe of the melting plate, and to transfer heat from said fins to said
20 melting plate. Suitable and exemplary, although clearly not the only possible heat fins are illustrated in US Patent Application 09/747,545, filed December 20, 2000, incorporated herein by reference

(0034) It is to be understood that the wick holder and associated secondary heat conductive elements are meant to be so situated and shaped as to en-
25 gage or interlock with a replaceable solid fuel element, such as by being of a specific shape or configuration that will engage or mate with a complementarily shaped fuel element. In a similar fashion, the melting plate and/or the fuel container may be formed in such a manner as to permit placement of fuel elements of specific configuration, such as wax pucks having a complementary configura-
30 tion, for example, in a preferred position in proximity to the heat conductive elements themselves, or to the wick holder, in such a manner as to maximize heat transfer from the melting plate to said fuel elements. In the most preferred em-

bodiment, secondary heat conductive elements are present both on the melting plate, and as an element of the wick holder. In said most preferred embodiment of the invention, there is a capillary lobe present on the melting plate, positioned in such a manner as to transfer heat to the fuel element, and configured so as to engage a wick holder holding a consumable wick and having one or more heat conductive fins, and a fuel element such as a wax puck. Further, the engagement of the wick holder with the capillary lobe is such as to provide a capillary effect between the two for feeding fuel to the wick. In this embodiment, the consumer may purchase a replacement fuel element comprising a wax puck and a wick holder and wick, configured so as to engage a matching capillary lobe on the melting plate in such a manner as to position the fuel element and the wick holder, and having a heat conductive element in the appropriate location to most efficiently melt the fuel element. Alternatively, the consumer may purchase an assembly comprising a wick holder and wick, with separately available appropriately shaped fuel elements.

(0035) The use of the melting plate technology of the present invention may also provide such advantages as elimination of tunneling, significant reduction of retention of wax at the conclusion of the burn, and elimination of walking or off-center wicks, while also giving a larger pool of liquid wax with a relatively small flame in a relatively short time period. In addition, the container may be of almost any shape desired, providing for great aesthetic possibilities. Since the fuel element, either alone or in combination with a wick and wick holder, may be provided as a separate unit, the consumer may be provided a great number of choices as to the color, content, and nature of the fuel, and the configuration of the fuel element may be varied to provide a large choice of shapes, such as seasonably decorative items. For example, shapes such as pumpkins may be provided for Halloween, wreaths for Christmas, and flowers for all seasons. In addition, the fuel element preferably is configured as to cooperatively engage both the melting plate and the wick holder, which wick holder in turn engages the capillary lobe on the melting plate, in such a manner as to provide the consumer the greatest degree of ease in placement of the fuel element in optimal position in the melting plate candle, with the least possibility of incorrect placement. Fur-

ther, the melting plate or support plate may have decorative features, such as designs, embossed, etched, printed, or stamped thereon.

(0036) Accordingly, the present invention provides a melting plate candle, wherein said candle comprises a container for a fuel element comprising a fuel
5 selected from the group consisting of paraffin, beeswax, montan wax, carnauba wax, microcrystalline wax, polyvinyl acetate, fatty alcohols, fatty acids, fatty esters, and gels incorporating such fuels, in a form selected from the group consisting of pucks, donuts, chips, slivers, balls, pellets, shavings, particulates, cubes, discs, three dimensional shapes, and wafers, or in any other suitable
10 shape. Said fuel element may optionally further comprise such volatile active materials as fragrances, air fresheners, deodorizers, odor eliminators, odor counter-actants, insecticides, insect repellants, herbals, medicinal substances, disinfectants, sanitizers, mood enhancers, aroma therapy compositions, and the like. Such solid fuel may be colored for decorative effect, if so desired, and may
15 be shaped to fit any given configuration of melting plate and/or wick holder. For example, the bottom of a solid fuel element should be curved complementarily to the shape of the melting plate upon which it is to rest, and have melting temperatures above ambient, but below the flame temperature of a wick burning such fuel.

20 (0037) These and still other advantages of the present invention will be apparent from the description which follows. The following description is merely of the preferred embodiments, and the claims should be looked to in order to understand the full scope of the invention.

(0038) Figures 1 and 2 illustrate the broad concept of a melting plate candle in its most basic form, such as set forth in Serial Number 09/747,545, filed
25 December 20, 2000, incorporated herein in its entirety by reference. The teachings of said pending patent application do not illustrate the capillary lobe and wick holder assembly of the present invention. As illustrated, a heat conductive melting plate container, 2, is provided, which transfers heat obtained from
30 the heat source, a flame (not shown) located on wick 3, by means of heat conduction, to the solid fuel element, 4, which rests upon the surface of the melting plate. For purposes of illustration, and for clarity, but intending no limitation, the

wick is illustrated as being of a relatively large diameter, rather than as a fibrous wick of small diameter. It is to be understood that the wick is positioned within and attached to the solid fuel element, 4, such as with a wick clip (not shown).

5 The melting plate, 2, as shown in Figures 1 and 2, is heated directly by the flame on the wick, 3, by radiation, as a result of the melting plate being shaped so as to have a portion, shoulder 18, in proximity to the flame, the diameter of the melting plate bowl being such as to permit the inner surfaces thereof to absorb appreciable amounts of heat from the flame.

(0039) The melting plate of Figures 1 and 2 is shaped so as to have a
10 raised outer shoulder, 18, thereby containing the resultant pool of melted fuel. It is to be understood that the melting plate may be in the form of a tray, bowl, concave plate, or other configuration which is capable of holding a pool of hot liquid fuel, and is preferably shaped so as to funnel or channel the liquified, i.e. melted, fuel to the wick. The melting plate may constitute a container in itself, as shown
15 in Figures 1, 2, 5, and 6, or may be surrounded by a separate container. In the embodiment shown in Figures 1 and 2, the melting plate rests upon a non-conductive base, 11, or legs of non-conductive or insulating material, so as to permit placement upon a table, counter, or other surface. The non-conductive base, as illustrated, comprises contact points, 12, so as to minimize the amount
20 of contact between the base and the melting plate, and to create an insulating air gap, 13, between the melting plate and the surface upon which the assembly rests.

(0040) The melting plate may be of any heat conductive material, such as brass, aluminum, steel, copper, stainless steel, silver, tin, bronze, zinc, iron, clad
25 materials, heat conductive polymers, ceramics, glass, or any other suitable heat conductive material or combination of such materials. As shown in Figure 2, the fuel is preferably located in direct contact with the surface of the melting plate, 2, which plate may, if desired, be constructed so as to have a non-conductive lower surface, so that the melting plate may rest upon a table surface or such. Such a
30 configuration may result from a clad material, a conductive melting plate material coated on the external surface with a non-conductive material, a non-conductive material having an insert of a heat conductive material, or other suitable ar-

rangements to permit the melting plate to be cool enough on the bottom surface to permit ease of handling, and/or placement upon surfaces not suitable for contact with heated bodies.

(0041) The wick, 3, preferably constitutes a conventional consumable
5 wicking material, such as such as cotton, cellulose, nylon, or paper, or the like,
which by capillary action will carry liquid fuel to the flame. Alternatively, non-
consumable wicks may comprise such materials as porous ceramics; porous
metals; fiber glass; metal fiber; compressed sand, glass, metal, or ceramic mi-
crospheres; foamed or porous glass, either natural or man-made, such as pum-
10 ice or perlite; gypsum; and chalk. However, for purposes of the present inven-
tion, the use of conventional consumable wicks is preferred. The wick, 3, may be
located in the center of the melting plate, 2, or may be off-center as desired, pro-
vided that the melting plate is configured so as to channel or funnel melted fuel to
said wick. The presence of two or more wicks is also within the scope of the pre-
15 sent invention. The wick is provided in conjunction with the wick holder assem-
bly, the preferred configuration of the wick holder being such as to cooperatively
engage a complimentarily shaped capillary lobe, 8, on the melting plate, as
shown in Figures 4 and 5, discussed hereinafter.

(0042) Illustrative of the wick holder assembly, and demonstrating key
20 safety features of the present invention, Figure 3 shows a configuration which
comprises the wick holder, 7, of the present invention utilized without a capillary
lobe located on a melting plate, but placed directly upon a solid surface, 16, such
as a table top. This drawing demonstrates that if the wick holder assembly of the
present invention were to be used in the absence of the melting plate and capil-
25 lary lobe configuration of the present invention, and with a solid fuel element, 4,
configured to fit the wick holder, 7, the candle would be self extinguishing. Here,
the wick, 3, having a flame, 1, thereupon, is held in place by wick retention
means, 5, in the wick holder, 7, which wick holder has weep holes, 14, therein.
The wick holder, 7, is shown as having been placed directly upon a hard surface,
30 16, such as a wooden table top. As shown, the melted wax, 15, resulting from
heat from the flame conductively and radiantly heating the wick holder, 7, passes
through the weep holes, 14, in the direction of arrows 17, to land and accumulate

on the surface 16. However, due to the fact that the wick, 3, terminates a considerable distance above the surface 16, the wick does not come into contact with the melted fuel, is thus not fed additional fuel, and extinguishes in a short period of time. For purposes of safety, it is preferred that the wick terminates at least 0.25, and preferably about 0.50 inches above the surface upon which the wick holder rests. The hard surface, 16, is for illustration purposes designated as being a wooden table top, but could as easily be a more flammable surface, such as a table cloth or sheet of paper.

(0043) In a melting plate candle apparatus of the invention, as shown in Figure 4, the wick, 3, is held in place by a heat conductive element, such as a wick holder, 7. To assure efficient heat exchange between the flame at the wick and the melting plate, the melting plate container, 2, has a portion, in this case a raised shoulder of the melting plate (not shown), which is in proximity to, and heated, such as by radiation, by the flame of the burning wick, which results in heat being transferred rapidly to the fuel by both conduction through the melting plate to the lower surfaces of the fuel, and by radiation from the flame to the upper surface of the fuel. The solid fuel element is thus subjected to melting both from heat from the flame and from the melting plate. As opposed to a conventional candle, transfer of heat from the flame to the fuel with a melting plate device is primarily by conduction, either through the melting plate or through additional heat conductive means, rather than by radiation, and is thus considerably more efficient, resulting in more rapid and more uniform melting of solid fuel and formation of a pool of liquid fuel, and a more efficient burn.

(0044) The preferred form of the concept, as illustrated in Figure 4, comprises a capillary lobe, 8, which functions to position a wick holder, 7, comprising a wick, 3, and a wick retention feature 5, upon the melting plate. As illustrated, the wick holder is configured so as to fit closely over the capillary lobe, and has weep holes or perforations, 14, in the top surface thereof whereby liquefied solid fuel may readily flow in the direction of arrows 17, to both the base of the wick 3, and into a starter recess bowl, 10, formed in the top of the capillary lobe, 8. The fuel refill element, 4, is configured so as to fit above and around the wick holder, 7, permitting wick 3 to pass through the central open portion of said fuel element,

where it is held in position by wick retention means, 5. In this position, the flame upon the wick heats, by radiant heat, both the fuel element 4, and the wick holder, 7, whereby the fuel element commences melting, and liquefied wax flows through the weep holes 14 to the starter recess bowl, 10, whereby it feeds to the wick for continued consumption. Simultaneously, melted wax flows down the sides of the wick holder, as indicated by arrows 17, to the melting plate, and to the capillary gap between the melting plate and the wick holder, whereby said melted wax is fed by capillary action to the recess bowl 10 and to the wick. Moreover, the heated melted fuel transfers heat to the surface of both the starter recess bowl and the wick holder, and thus to the melting plate.

(0045) In Figure 5, an exploded perspective view of the invention is shown, with a bowl shaped melting plate container, 2, which comprises a capillary lobe, 8, located in approximately the center thereof. A wick holder, 7, is shown above the capillary lobe, the wick holder being shaped in such a manner as to fit closely over said capillary lobe. The wick holder, as illustrated, further comprises the wick, 3, and a heat fin, 9. A solid fuel element, 4, is shown, having a cut out portion through which the heat fin and wick assembly may pass, so as to place the wick in close proximity to a fuel starter bump, 6, on the top surface of said fuel element. The solid fuel element is shown as a wax puck, although other shapes may clearly be used within the scope of the present invention. Since difficulty in lighting the wick may be encountered, a starter bump of fuel, 6, may be provided in close proximity to the wick, 3. As illustrated in Figures 1, 2, 5, 6, and 8, this bump is most easily molded directly into the shape of the fuel element, and provides a ready source of liquid fuel to the wick when a match or other appropriate source of flame is employed to start the wick burning, which source of flame will melt the starting bump to thus create an initial pool of liquid fuel.

(0046) Figure 6 shows the embodiment of Figure 5 in operational configuration, showing the relationship of the elements in position for lighting of the wick, 3, wherein the melting plate, 2, is shown with a fuel element, 4, positioned on the capillary lobe (8, not visible) and centered around a wick holder assembly with the heat transfer fin, 9, and wick, 3, extending above the puck adjacent the starter bump, 6.

(0047) Figure 7 is a close-up view of the wick holder assembly, 7, showing the heat fin, 9, and wick 3, held in position by wick retention means 5.

(0048) Figure 8 shows the wick holder assembly of Figure 7, in conjunction with a solid fuel element 4, illustrating the manner in which refill units
5 for the melting plate candle are normally provided, showing the wax puck in cooperative relationship to wick 3, fins 9, and starter bump 6.

(0049) Thus, when using a solid fuel, such as wax, in conjunction with a heat conductive wick holder, solid fuel refill units may be shaped to fit the shape of the melting plate, with a "lock and key" relationship to the wick holder and
10 hence to the melting plate. For example, the melting plate may be a decoratively shaped container, and wax may be provided in the form of refills specific for the container shape selected, such as round, square, oval, rectangular, triangular, or otherwise, so shaped that the wick holder assembly incorporated with the wax refill unit will fit and engage a complementarily shaped capillary lobe.

(0050) The use of a melting plate with additional heat conductive elements, such as the heat fins illustrated, offers a number of distinct advantages. First, it permits a larger pool of liquid fuel, due to improved heat conduction into the fuel, which results in more rapid formation of the pool. This in turn allows better regulation of the size and shape, as well as the temperature, volume, and
20 depth of the liquified wax pool to allow more efficient use of fuels present. In fact, melting plates of the present invention permit ease of refill, with little or no cleaning. In most instances, no cleaning is required, but if desired, the plate may be conveniently washed in a manner such as a dish, plate or bowl is washed, in a wash basin or in a dishwasher. The use of a capillary lobe in the
25 heat plate, in conjunction with heat fins on the wick holder, also reduces or eliminates retention of solidified excess fuel when the candle is allowed to burn itself out, and permits more complete and uniform burning of fuel elements which are other than round, i.e. square, oval, triangular, or in the shape of a flower or decorative object, etc. Further, the melting plate technology in conjunction with a capillary lobe and complimentary wick holder, results in devices which may be self
30 extinguishing, and improvements in or elimination of typical burning problems encountered with candles, such as tunneling, drowning, collapsing, cratering, and

wick drift. Candles utilizing the melting plate technology of the present invention are also more forgiving of formulation or process variances.

(0051) A number of small votive candles were prepared to test the efficiency of the invention relative to heat distribution and melting of the wax fuel. In the following Examples, all candles were comprised of 12 grams of the same wax (having a melting point of 130° F.), and were of the same dimension, with identical consumable wicks. Comparative examples comprised votive candles having a finned wick holder located upon a heat plate, and votive candles with a finned wick holder located upon a heat plate incorporating a capillary lobe as set forth in the present invention. Temperatures of the wax pool were measured at distances of 10 and 20 mm from the wick, using identical infrared temperature measuring methods in all examples.

(0052) In this experiment, votive candles with a finned holder absent a capillary lobe burned out after 125 minutes, and the votive candle with a finned holder and capillary lobe of the present invention burned out at about 115 minutes. It may be seen from the table, however, that the candle employing the combination of the wick holder and capillary lobe, as set forth in the present invention, achieved a higher temperature at a significantly earlier time than the candle employing a wick clip but no capillary lobe, at distances of both 10 mm and 20 mm from the wick. That is, the capillary lobe embodiment achieved higher wax pool temperatures at any given time and distance than the embodiment without the capillary lobe, demonstrating the very rapid heating effect of the present invention resulting from heat distribution through the melting plate. The pool temperatures, at both 10mm and 20mm from the wick, were higher than any previously observed for this type of wax after 10 minutes of burn time. It is to be noted that the rate of heating achieved and the rapidity of liquefaction, which result in a rapid melt of the entire fuel supply, and an increased surface area of melted fuel, in a much shorter time frame, assure a more rapid release of any volatile active materials present in the fuel. The higher temperatures achieved are also to be noted, for the same reasons. It is also evident that these factors may be effected by the size and shape of the capillary lobe employed, and that the lobe permits more rapid transfer of heat from the wick clip to the melting plate

as a result of a greater surface area and the presence of vertically oriented surfaces, as well as by choice of material of the melting plate, the capillary lobe, and the heat fins.

5 Table

Time versus Temperature at Distance from Wick				
	10 mm from Wick		20 mm from Wick	
Minutes	Finned Clip, Heat Plate	This Invention	Finned Clip, Heat Plate	This Invention
10	115	176	79	146
15	121	167	83	139
20	128	182	87	166
25	136	193	89	182
30	144	200	91	190
40	128	205	93	191
50	146	209	130	190
60	177	210	165	188
70	203	210	172	186
80	208	210	174	177
90	200	210	167	176

(0053) While the present invention has been described with respect to what are at present considered to be the preferred embodiments, it is to be understood that the invention is not to be limited to the disclosed embodiments. To the contrary, the invention is intended to cover various modifications and equivalent arrangements within the spirit and scope of the appended claims. The scope of the following claims is to be accorded the broadest interpretation so as to encompass all such modifications and equivalent formulations and functions.

INDUSTRIAL APPLICABILITY

(0054) The melting plate and heat conductive element candles of the present invention, utilizing a capillary lobe and correspondingly shaped wick holder,
5 can be used in connection with a large variety of solid fuels. The conductive materials of which the melting plate and heat fins may be constructed are commonly available, and the various configurations are readily produced. There is considerable interest for candles having extended burn times, and for refillable candles or solid fuel lamps.
